

**System and Method for
Manipulating Data with a Plurality of Processors**

BACKGROUND OF THE INVENTION

1. Technical Field

5 The present invention relates in general to a system
and method for manipulating data using a plurality of
processors. In particular, the present invention relates
to a system and a method for sharing data among a plurality
of heterogeneous processors by the processors sharing a
10 common memory.

2. Description of the Related Art

 Adding processors to a computer system is a common
approach for increasing a computer system's processing
speed. The multiple processors are typically configured to
15 process data in parallel and thus significantly reduce task
execution time.

 In many instances, the multiple processors may be
dissimilar with each processor specializing in a particular
processing task. The dissimilar processors typically each
20 must have their own random access memory (RAM) units, which
makes the sharing of data between the processors difficult.
In many instances of parallel processing, the results from
one computation by one processor are dependent on another
computation by another processor. As a result, a large
25 amount of data must be transferred between the processors
or between each of the processors and a central memory
location.

The large data transfers can significantly reduce the benefits gained by having the multiple processors. What is needed, therefore, is a system and method that could reduce the required data transferring and thus increase the computational performance of the system. The system and method should provide the user with the capability to communicate data and results between multiple processors—even dissimilar processors—to avoid the degradation of performance associated with the transferring of large data between the multiple processors of a computer system.

SUMMARY

It has been discovered that the aforementioned challenges can be addressed by a method and a system having a plurality of heterogeneous processors sharing a common memory thereby sharing data between the processors through the common memory.

The data to be processed are loaded into a common memory shared by a main processor and a plurality of secondary processors. The data may be loaded into the common memory by a main processor, which divides the data to be processed into data blocks. The size of the data blocks may be equal to the size of the registers of the secondary processors to facilitate processing of the data blocks by the secondary processors.

The main processor may then identify an available secondary processor to process the first data block. The main processor notifies the secondary processor that a block of data requires processing, and in addition, the main processor provides the secondary processor with instructions on how to process the data block. The secondary processor may transfer the data block to the secondary processor's local store using direct memory access (DMA) commands and then to the secondary processor's registers for processing. The secondary processor returns the processed data to the secondary processor's local store and then back to the common system memory using a DMA command.

The main processor may continue identifying available secondary processors and requesting the available secondary processors to process data blocks until all the data blocks have been processed.

5 The foregoing is a summary and thus contains, by necessity, simplifications, generalizations, and omissions of detail; consequently, those skilled in the art will appreciate that the summary is illustrative only and is not intended to be in any way limiting. Other aspects,
10 inventive features, and advantages of the present invention, as defined solely by the claims, will become apparent in the non-limiting detailed description set forth below.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION

The following is intended to provide a detailed description of an example of the invention and should not be taken to be limiting of the invention itself. Rather,
5 any number of variations may fall within the scope of the invention defined in the claims following the description.

The overall architecture for a computer system 101 in accordance with the present invention is shown in **Figure 1**.

As illustrated in this figure, system 101 includes
10 network 104 to which is connected a plurality of computers and computing devices. Network 104 can be a LAN, a global network, such as the Internet, or any other computer network.

The computers and computing devices connected to
15 network 104 (the network's "members") include, e.g., client computers 106, server computers 108, personal digital assistants (PDAs) 110, digital television (DTV) 112 and other wired or wireless computers and computing devices. The processors employed by the members of network 104 are
20 constructed from the same common computing module. These processors also preferably all have the same ISA and perform processing in accordance with the same instruction set. The number of modules included within any particular processor depends upon the processing power required by
25 that processor.

For example, since servers 108 of system 101 perform more processing of data and applications than clients 106,

servers 108 contain more computing modules than clients 106. PDAs 110, on the other hand, perform the least amount of processing. PDAs 110, therefore, contain the smallest number of computing modules. DTV 112 performs a level of processing between that of clients 106 and servers 108. DTV 112, therefore, contains a number of computing modules between that of clients 106 and servers 108. As discussed below, each computing module contains a processing controller and a plurality of identical processing units for performing parallel processing of the data and applications transmitted over network 104.

This homogeneous configuration for system 101 facilitates adaptability, processing speed and processing efficiency. Because each member of system 101 performs processing using one or more (or some fraction) of the same computing module, the particular computer or computing device performing the actual processing of data and applications is unimportant. The processing of a particular application and data, moreover, can be shared among the network's members. By uniquely identifying the cells comprising the data and applications processed by system 101 throughout the system, the processing results can be transmitted to the computer or computing device requesting the processing regardless of where this processing occurred. Because the modules performing this processing have a common structure and employ a common ISA, the computational burdens of an added layer of software to achieve compatibility among the processors is avoided. This architecture and programming model facilitates the processing speed necessary to execute, e.g., real-time, multimedia applications.

To take further advantage of the processing speeds and efficiencies facilitated by system 101, the data and applications processed by this system are packaged into uniquely identified, uniformly formatted software cells

5 102. Each software cell 102 contains, or can contain, both applications and data. Each software cell also contains an ID to globally identify the cell throughout network 104 and system 101. This uniformity of structure for the software cells, and the software cells' unique identification

10 throughout the network, facilitates the processing of applications and data on any computer or computing device of the network. For example, a client 106 may formulate a software cell 102 but, because of the limited processing capabilities of client 106, transmit this software cell to

15 a server 108 for processing. Software cells can migrate, therefore, throughout network 104 for processing on the basis of the availability of processing resources on the network.

The homogeneous structure of processors and software

20 cells of system 101 also avoids many of the problems of today's heterogeneous networks. For example, inefficient programming models which seek to permit processing of applications on any ISA using any instruction set, e.g., virtual machines such as the Java virtual machine, are

25 avoided. System 101, therefore, can implement broadband processing far more effectively and efficiently than today's networks.

The basic processing module for all members of network 104 is the processing unit (PU). **Figure 2** illustrates the

30 structure of a PU. As shown in this figure, PU 201

comprises a processing unit (PU) 203, a direct memory access controller (DMAC) 205 and a plurality of synergistic processing units (SPUs), namely, SPU 207, SPU 209, SPU 211, SPU 213, SPU 215, SPU 217, SPU 219 and SPU 221. A local PU bus 223 transmits data and applications among the SPUs, DMAC 205 and PU 203. Local PU bus 223 can have, e.g., a conventional architecture or be implemented as a packet switch network. Implementation as a packet switch network, while requiring more hardware, increases available bandwidth.

PU 201 can be constructed using various methods for implementing digital logic. PU 201 preferably is constructed, however, as a single integrated circuit employing a complementary metal oxide semiconductor (CMOS) on a silicon substrate. Alternative materials for substrates include gallium arsenide, gallium aluminum arsenide and other so-called III-B compounds employing a wide variety of dopants. PU 201 also could be implemented using superconducting material, e.g., rapid single-flux-quantum (RSFQ) logic.

PU 201 is closely associated with a dynamic random access memory (DRAM) 225 through a high bandwidth memory connection 227. DRAM 225 functions as the main memory for PU 201. Although a DRAM 225 preferably is a dynamic random access memory, DRAM 225 could be implemented using other means, e.g., as a static random access memory (SRAM), a magnetic random access memory (MRAM), an optical memory or a holographic memory. DMAC 205 facilitates the transfer of data between DRAM 225 and the SPUs and PU of PU 201. As further discussed below, DMAC 205 designates for each SPU

an exclusive area in DRAM 225 into which only the SPU can write data and from which only the SPU can read data. This exclusive area is designated a "sandbox."

5 PU 203 can be, e.g., a standard processor capable of stand-alone processing of data and applications. In operation, PU 203 schedules and orchestrates the processing of data and applications by the SPUs. The SPUs preferably are single instruction, multiple data (SIMD) processors. Under the control of PU 203, the SPUs perform the
10 processing of these data and applications in a parallel and independent manner. DMAC 205 controls accesses by PU 203 and the SPUs to the data and applications stored in the shared DRAM 225. Although PU 201 preferably includes eight SPUs, a greater or lesser number of SPUs can be employed in
15 a PU depending upon the processing power required. Also, a number of PUs, such as PU 201, may be joined or packaged together to provide enhanced processing power.

 For example, as shown in **Figure 3**, four PUs may be packaged or joined together, e.g., within one or more chip
20 packages, to form a single processor for a member of network 104. This configuration is designated a broadband engine (BE). As shown in **Figure 3**, BE 301 contains four PUs, namely, PU 303, PU 305, PU 307 and PU 309. Communications among these PUs are over BE bus 311. Broad
25 bandwidth memory connection 313 provides communication between shared DRAM 315 and these PUs. In lieu of BE bus 311, communications among the PUs of BE 301 can occur through DRAM 315 and this memory connection.

Input/output (I/O) interface 317 and external bus 319 provide communications between broadband engine 301 and the other members of network 104. Each PU of BE 301 performs processing of data and applications in a parallel and independent manner analogous to the parallel and independent processing of applications and data performed by the SPUs of a PU.

Figure 4 illustrates the structure of an SPU. SPU 402 includes local memory 406, registers 410, four floating point units 412 and four integer units 414. Again, however, depending upon the processing power required, a greater or lesser number of floating points units 412 and integer units 414 can be employed. In a preferred embodiment, local memory 406 contains 128 kilobytes of storage, and the capacity of registers 410 is 128.times.128 bits. Floating point units 412 preferably operate at a speed of 32 billion floating point operations per second (32 GFLOPS), and integer units 414 preferably operate at a speed of 32 billion operations per second (32 GOPS).

Local memory 406 is not a cache memory. Local memory 406 is preferably constructed as an SRAM. Cache coherency support for an SPU is unnecessary. A PU may require cache coherency support for direct memory accesses initiated by the PU. Cache coherency support is not required, however, for direct memory accesses initiated by an SPU or for accesses from and to external devices.

SPU 402 further includes bus 404 for transmitting applications and data to and from the SPU. In a preferred embodiment, this bus is 1,024 bits wide. SPU 402 further

includes internal busses 408, 420 and 418. In a preferred embodiment, bus 408 has a width of 256 bits and provides communications between local memory 406 and registers 410. Busses 420 and 418 provide communications between, respectively, registers 410 and floating point units 412, and registers 410 and integer units 414. In a preferred embodiment, the width of busses 418 and 420 from registers 410 to the floating point or integer units is 384 bits, and the width of busses 418 and 420 from the floating point or integer units to registers 410 is 128 bits. The larger width of these busses from registers 410 to the floating point or integer units than from these units to registers 410 accommodates the larger data flow from registers 410 during processing. A maximum of three words are needed for each calculation. The result of each calculation, however, normally is only one word.

Figures. 5-10 further illustrate the modular structure of the processors of the members of network 104. For example, as shown in **Figure 5**, a processor may comprise a single PU 502. As discussed above, this PU typically comprises a PU, DMAC and eight SPUs. Each SPU includes local storage (LS) . On the other hand, a processor may comprise the structure of visualizer (VS) 505. As shown in **Figure 5**, VS 505 comprises PU 512, DMAC 514 and four SPUs, namely, SPU 516, SPU 518, SPU 520 and SPU 522. The space within the chip package normally occupied by the other four SPUs of a PU is occupied in this case by pixel engine 508, image cache 510 and cathode ray tube controller (CRTC) 504. Depending upon the speed of communications required for PU 502 or VS 505, optical interface 506 also may be included on the chip package.

Using this standardized, modular structure, numerous other variations of processors can be constructed easily and efficiently. For example, the processor shown in **Figure 6** comprises two chip packages, namely, chip package 602 comprising a BE and chip package 604 comprising four VSs. Input/output (I/O) 606 provides an interface between the BE of chip package 602 and network 104. Bus 608 provides communications between chip package 602 and chip package 604. Input output processor (IOP) 610 controls the flow of data into and out of I/O 606. I/O 606 may be fabricated as an application specific integrated circuit (ASIC). The output from the VSs is video signal 612.

Figure 7 illustrates a chip package for a BE 702 with two optical interfaces 704 and 706 for providing ultra high speed communications to the other members of network 104 (or other chip packages locally connected). BE 702 can function as, e.g., a server on network 104.

The chip package of **Figure 8** comprises two PUs 802 and 804 and two VSs 806 and 808. An I/O 810 provides an interface between the chip package and network 104. The output from the chip package is a video signal. This configuration may function as, e.g., a graphics work station.

Figure 9 illustrates yet another configuration. This configuration contains one-half of the processing power of the configuration illustrated in **Figure 8**. Instead of two PUs, one PU 902 is provided, and instead of two VSs, one VS 904 is provided. I/O 906 has one-half the bandwidth of the

I/O illustrated in **Figure 8**. Such a processor also may function, however, as a graphics work station.

A final configuration is shown in **Figure 10**. This processor consists of only a single VS **1002** and an I/O
5 **1004**. This configuration may function as, e.g., a PDA.

Figure 11A illustrates the integration of optical interfaces into a chip package of a processor of network 104. These optical interfaces convert optical signals to electrical signals and electrical signals to optical
10 signals and can be constructed from a variety of materials including, e.g., gallium arsinide, aluminum gallium arsinide, germanium and other elements or compounds. As shown in this figure, optical interfaces **1104** and **1106** are fabricated on the chip package of BE **1102**. BE bus **1108**
15 provides communication among the PUs of BE **1102**, namely, PU **1110**, PU **1112**, PU **1114**, PU **1116**, and these optical interfaces. Optical interface **1104** includes two ports, namely, port **1118** and port **1120**, and optical interface **1106** also includes two ports, namely, port **1122** and port **1124**.
20 Ports **1118**, **1120**, **1122** and **1124** are connected to, respectively, optical wave guides **1126**, **1128**, **1130** and **1132**. Optical signals are transmitted to and from BE **1102** through these optical wave guides via the ports of optical interfaces **1104** and **1106**.

25 plurality of BEs can be connected together in various configurations using such optical wave guides and the four optical ports of each BE. For example, as shown in **Figure 11B**, two or more BEs, e.g., BE **1152**, BE **1154** and BE **1156**, can be connected serially through such optical ports. In

this example, optical interface **1166** of BE **1152** is connected through its optical ports to the optical ports of optical interface **1160** of BE **1154**. In a similar manner, the optical ports of optical interface **1162** on BE **1154** are
5 connected to the optical ports of optical interface **1164** of BE **1156**.

A matrix configuration is illustrated in **Figure 11C**. In this configuration, the optical interface of each BE is connected to two other BEs. As shown in this figure, one of
10 the optical ports of optical interface **1188** of BE **1172** is connected to an optical port of optical interface **1182** of BE **1176**. The other optical port of optical interface **1188** is connected to an optical port of optical interface **1184** of BE **1178**. In a similar manner, one optical port of
15 optical interface **1190** of BE **1174** is connected to the other optical port of optical interface **1184** of BE **1178**. The other optical port of optical interface **1190** is connected to an optical port of optical interface **1186** of BE **1180**. This matrix configuration can be extended in a similar
20 manner to other BEs.

Using either a serial configuration or a matrix configuration, a processor for network 104 can be constructed of any desired size and power. Of course, additional ports can be added to the optical interfaces of
25 the BEs, or to processors having a greater or lesser number of PUs than a BE, to form other configurations.

Figure 12A illustrates the control system and structure for the DRAM of a BE. A similar control system and structure is employed in processors having other sizes

and containing more or less PUs. As shown in this figure, a cross-bar switch connects each DMAC **1210** of the four PUs comprising BE **1201** to eight bank controls **1206**. Each bank control **1206** controls eight banks **1208** (only four are shown in the figure) of DRAM **1204**. DRAM **1204**, therefore, comprises a total of sixty-four banks. In a preferred embodiment, DRAM **1204** has a capacity of 64 megabytes, and each bank has a capacity of 1 megabyte. The smallest addressable unit within each bank, in this preferred embodiment, is a block of **1024** bits.

BE **1201** also includes switch unit **1212**. Switch unit **1212** enables other SPUs on BEs closely coupled to BE **1201** to access DRAM **1204**. A second BE, therefore, can be closely coupled to a first BE, and each SPU of each BE can address twice the number of memory locations normally accessible to an SPU. The direct reading or writing of data from or to the DRAM of a first BE from or to the DRAM of a second BE can occur through a switch unit such as switch unit **1212**.

For example, as shown in **Figure 12B**, to accomplish such writing, the SPU of a first BE, e.g., SPU **1220** of BE **1222**, issues a write command to a memory location of a DRAM of a second BE, e.g., DRAM **1228** of BE **1226** (rather than, as in the usual case, to DRAM **1224** of BE **1222**). DMAC **1230** of BE **1222** sends the write command through cross-bar switch **1221** to bank control **1234**, and bank control **1234** transmits the command to an external port **1232** connected to bank control **1234**. DMAC **1238** of BE **1226** receives the write command and transfers this command to switch unit **1240** of BE **1226**. Switch unit **1240** identifies the DRAM address contained in the write command and sends the data for

storage in this address through bank control **1242** of BE **1226** to bank **1244** of DRAM **1228**. Switch unit **1240**, therefore, enables both DRAM **1224** and DRAM **1228** to function as a single memory space for the SPUs of BE **1226**.

5 **Figure 13** shows the configuration of the sixty-four banks of a DRAM. These banks are arranged into eight rows, namely, rows **1302**, **1304**, **1306**, **1308**, **1310**, **1312**, **1314** and **1316** and eight columns, namely, columns **1320**, **1322**, **1324**, **1326**, **1328**, **1330**, **1332** and **1334**. Each row is controlled by
10 a bank controller. Each bank controller, therefore, controls eight megabytes of memory.

 Figures. 14A and 14B illustrate different configurations for storing and accessing the smallest addressable memory unit of a DRAM, e.g., a block of **1024**
15 bits. In **Figure 14A**, DMAC **1402** stores in a single bank **1404** eight **1024** bit blocks **1406**. In **Figure 14B**, on the other hand, while DMAC **1412** reads and writes blocks of data containing **1024** bits, these blocks are interleaved between two banks, namely, bank **1414** and bank **1416**. Each of these
20 banks, therefore, contains sixteen blocks of data, and each block of data contains 512 bits. This interleaving can facilitate faster accessing of the DRAM and is useful in the processing of certain applications.

Figure 15 illustrates the architecture for a DMAC **1504**
25 within a PU. As illustrated in this figure, the structural hardware comprising DMAC **1506** is distributed throughout the PU such that each SPU **1502** has direct access to a structural node **1504** of DMAC **1506**. Each node executes the

logic appropriate for memory accesses by the SPU to which the node has direct access.

Figure 16 shows an alternative embodiment of the DMAC, namely, a non-distributed architecture. In this case, the structural hardware of DMAC **1606** is centralized. SPU **1602** and PU **1604** communicate with DMAC **1606** via local PU bus **1607**. DMAC **1606** is connected through a cross-bar switch to a bus **1608**. Bus **1608** is connected to DRAM **1610**.

As discussed above, all of the multiple SPUs of a PU can independently access data in the shared DRAM. As a result, a first SPU could be operating upon particular data in its local storage at a time during which a second SPU requests these data. If the data were provided to the second SPU at that time from the shared DRAM, the data could be invalid because of the first SPU's ongoing processing which could change the data's value. If the second processor received the data from the shared DRAM at that time, therefore, the second processor could generate an erroneous result. For example, the data could be a specific value for a global variable. If the first processor changed that value during its processing, the second processor would receive an outdated value. A scheme is necessary, therefore, to synchronize the SPUs' reading and writing of data from and to memory locations within the shared DRAM. This scheme must prevent the reading of data from a memory location upon which another SPU currently is operating in its local storage and, therefore, which are not current, and the writing of data into a memory location storing current data.

To overcome these problems, for each addressable memory location of the DRAM, an additional segment of memory is allocated in the DRAM for storing status information relating to the data stored in the memory location. This status information includes a full/empty (F/E) bit, the identification of an SPU (SPU ID) requesting data from the memory location and the address of the SPU's local storage (LS address) to which the requested data should be read. An addressable memory location of the DRAM can be of any size. In a preferred embodiment, this size is **1024** bits.

The setting of the F/E bit to 1 indicates that the data stored in the associated memory location are current. The setting of the F/E bit to 0, on the other hand, indicates that the data stored in the associated memory location are not current. If an SPU requests the data when this bit is set to 0, the SPU is prevented from immediately reading the data. In this case, an SPU ID identifying the SPU requesting the data, and an LS address identifying the memory location within the local storage of this SPU to which the data are to be read when the data become current, are entered into the additional memory segment.

An additional memory segment also is allocated for each memory location within the local storage of the SPUs. This additional memory segment stores one bit, designated the "busy bit." The busy bit is used to reserve the associated LS memory location for the storage of specific data to be retrieved from the DRAM. If the busy bit is set to 1 for a particular memory location in local storage, the SPU can use this memory location only for the writing of

these specific data. On the other hand, if the busy bit is set to 0 for a particular memory location in local storage, the SPU can use this memory location for the writing of any data.

5 Examples of the manner in which the F/E bit, the SPU ID, the LS address and the busy bit are used to synchronize the reading and writing of data from and to the shared DRAM of a PU are illustrated in Figures. 17-31.

10 As shown in **Figure 17**, one or more PUs, e.g., PU **1720**, interact with DRAM **1702**. PU **1720** includes SPU **1722** and SPU **1740**. SPU **1722** includes control logic **1724**, and SPU **1740** includes control logic **1742**. SPU **1722** also includes local storage **1726**. This local storage includes a plurality of addressable memory locations **1728**. SPU **1740** includes local storage **1744**, and this local storage also includes a plurality of addressable memory locations **1746**. All of these addressable memory locations preferably are **1024** bits in size.

20 An additional segment of memory is associated with each LS addressable memory location. For example, memory segments **1729** and **1734** are associated with, respectively, local memory locations **1731** and **1732**, and memory segment **1752** is associated with local memory location **1750**. A "busy bit," as discussed above, is stored in each of these additional memory segments. Local memory location **1732** is shown with several Xs to indicate that this location contains data.

25

DRAM **1702** contains a plurality of addressable memory locations **1704**, including memory locations **1706** and **1708**. These memory locations preferably also are **1024** bits in size. An additional segment of memory also is associated with each of these memory locations. For example, additional memory segment **1760** is associated with memory location **1706**, and additional memory segment **1762** is associated with memory location **1708**. Status information relating to the data stored in each memory location is stored in the memory segment associated with the memory location. This status information includes, as discussed above, the F/E bit, the SPU ID and the LS address. For example, for memory location **1708**, this status information includes F/E bit **1712**, SPU ID **1714** and LS address **1716**.

Using the status information and the busy bit, the synchronized reading and writing of data from and to the shared DRAM among the SPUs of a PU, or a group of PUs, can be achieved.

Figure 18 illustrates the initiation of the synchronized writing of data from LS memory location **1732** of SPU **1722** to memory location **1708** of DRAM **1702**. Control **1724** of SPU **1722** initiates the synchronized writing of these data. Since memory location **1708** is empty, F/E bit **1712** is set to 0. As a result, the data in LS location **1732** can be written into memory location **1708**. If this bit were set to 1 to indicate that memory location **1708** is full and contains current, valid data, on the other hand, control **1722** would receive an error message and be prohibited from writing data into this memory location.

The result of the successful synchronized writing of the data into memory location **1708** is shown in **Figure 19**. The written data are stored in memory location **1708**, and F/E bit **1712** is set to 1. This setting indicates that
5 memory location **1708** is full and that the data in this memory location are current and valid.

Figure 20 illustrates the initiation of the synchronized reading of data from memory location **1708** of DRAM **1702** to LS memory location **1750** of local storage **1744**.
10 To initiate this reading, the busy bit in memory segment **1752** of LS memory location **1750** is set to 1 to reserve this memory location for these data. The setting of this busy bit to 1 prevents SPU **1740** from storing other data in this memory location.

15 As shown in **Figure 21**, control logic **1742** next issues a synchronize read command for memory location **1708** of DRAM **1702**. Since F/E bit **1712** associated with this memory location is set to 1, the data stored in memory location **1708** are considered current and valid. As a result, in
20 preparation for transferring the data from memory location **1708** to LS memory location **1750**, F/E bit **1712** is set to 0. This setting is shown in **Figure 22**. The setting of this bit to 0 indicates that, following the reading of these data, the data in memory location **1708** will be invalid.

25 As shown in **Figure 23**, the data within memory location **1708** next are read from memory location **1708** to LS memory location **1750**. **Figure 24** shows the final state. A copy of the data in memory location **1708** is stored in LS memory location **1750**. F/E bit **1712** is set to 0 to indicate that

the data in memory location **1708** are invalid. This invalidity is the result of alterations to these data to be made by SPU **1740**. The busy bit in memory segment **1752** also is set to 0. This setting indicates that LS memory location **1750** now is available to SPU **1740** for any purpose, i.e., this LS memory location no longer is in a reserved state waiting for the receipt of specific data. LS memory location **1750**, therefore, now can be accessed by SPU **1740** for any purpose.

Figures. 25-31 illustrate the synchronized reading of data from a memory location of DRAM **1702**, e.g., memory location **1708**, to an LS memory location of an SPU's local storage, e.g., LS memory location **1752** of local storage **1744**, when the F/E bit for the memory location of DRAM **1702** is set to 0 to indicate that the data in this memory location are not current or valid. As shown in **Figure 25**, to initiate this transfer, the busy bit in memory segment **1752** of LS memory location **1750** is set to 1 to reserve this LS memory location for this transfer of data. As shown in **Figure 26**, control logic **1742** next issues a synchronize read command for memory location **1708** of DRAM **1702**. Since the F/E bit associated with this memory location, F/E bit **1712**, is set to 0, the data stored in memory location **1708** are invalid. As a result, a signal is transmitted to control logic **1742** to block the immediate reading of data from this memory location.

As shown in **Figure 27**, the SPU ID **1714** and LS address **1716** for this read command next are written into memory segment **1762**. In this case, the SPU ID for SPU **1740** and the LS memory location for LS memory location **1750** are written

into memory segment **1762**. When the data within memory location **1708** become current, therefore, this SPU ID and LS memory location are used for determining the location to which the current data are to be transmitted.

5 The data in memory location **1708** become valid and current when an SPU writes data into this memory location. The synchronized writing of data into memory location **1708** from, e.g., memory location **1732** of SPU **1722**, is illustrated in **Figure 28**. This synchronized writing of
10 these data is permitted because F/E bit **1712** for this memory location is set to 0.

 As shown in **Figure 29**, following this writing, the data in memory location **1708** become current and valid. SPU ID **1714** and LS address **1716** from memory segment **1762**,
15 therefore, immediately are read from memory segment **1762**, and this information then is deleted from this segment. F/E bit **1712** also is set to 0 in anticipation of the immediate reading of the data in memory location **1708**. As shown in **Figure 30**, upon reading SPU ID **1714** and LS address **1716**,
20 this information immediately is used for reading the valid data in memory location **1708** to LS memory location **1750** of SPU **1740**. The final state is shown in **Figure 31**. This figure shows the valid data from memory location **1708** copied to memory location **1750**, the busy bit in memory
25 segment **1752** set to 0 and F/E bit **1712** in memory segment **1762** set to 0. The setting of this busy bit to 0 enables LS memory location **1750** now to be accessed by SPU **1740** for any purpose. The setting of this F/E bit to 0 indicates that the data in memory location **1708** no longer are current and
30 valid.

Figure 32 summarizes the operations described above and the various states of a memory location of the DRAM based upon the states of the F/E bit, the SPU ID and the LS address stored in the memory segment corresponding to the memory location. The memory location can have three states. These three states are an empty state **3280** in which the F/E bit is set to 0 and no information is provided for the SPU ID or the LS address, a full state **3282** in which the F/E bit is set to 1 and no information is provided for the SPU ID or LS address and a blocking state **3284** in which the F/E bit is set to 0 and information is provided for the SPU ID and LS address.

As shown in this figure, in empty state **3280**, a synchronized writing operation is permitted and results in a transition to full state **3282**. A synchronized reading operation, however, results in a transition to the blocking state **3284** because the data in the memory location, when the memory location is in the empty state, are not current.

In full state **3282**, a synchronized reading operation is permitted and results in a transition to empty state **3280**. On the other hand, a synchronized writing operation in full state **3282** is prohibited to prevent overwriting of valid data. If such a writing operation is attempted in this state, no state change occurs and an error message is transmitted to the SPU's corresponding control logic.

In blocking state **3284**, the synchronized writing of data into the memory location is permitted and results in a transition to empty state **3280**. On the other hand, a synchronized reading operation in blocking state **3284** is

prohibited to prevent a conflict with the earlier
synchronized reading operation which resulted in this
state. If a synchronized reading operation is attempted in
blocking state **3284**, no state change occurs and an error
5 message is transmitted to the SPU's corresponding control
logic.

The scheme described above for the synchronized
reading and writing of data from and to the shared DRAM
also can be used for eliminating the computational
10 resources normally dedicated by a processor for reading
data from, and writing data to, external devices. This
input/output (I/O) function could be performed by a PU.
However, using a modification of this synchronization
scheme, an SPU running an appropriate program can perform
15 this function. For example, using this scheme, a PU
receiving an interrupt request for the transmission of data
from an I/O interface initiated by an external device can
delegate the handling of this request to this SPU. The SPU
then issues a synchronize write command to the I/O
20 interface. This interface in turn signals the external
device that data now can be written into the DRAM. The SPU
next issues a synchronize read command to the DRAM to set
the DRAM's relevant memory space into a blocking state. The
SPU also sets to 1 the busy bits for the memory locations
25 of the SPU's local storage needed to receive the data. In
the blocking state, the additional memory segments
associated with the DRAM's relevant memory space contain
the SPU's ID and the address of the relevant memory
locations of the SPU's local storage. The external device
30 next issues a synchronize write command to write the data
directly to the DRAM's relevant memory space. Since this

memory space is in the blocking state, the data are immediately read out of this space into the memory locations of the SPU's local storage identified in the additional memory segments. The busy bits for these memory locations then are set to 0. When the external device completes writing of the data, the SPU issues a signal to the PU that the transmission is complete.

Using this scheme, therefore, data transfers from external devices can be processed with minimal computational load on the PU. The SPU delegated this function, however, should be able to issue an interrupt request to the PU, and the external device should have direct access to the DRAM.

The DRAM of each PU includes a plurality of "sandboxes." A sandbox defines an area of the shared DRAM beyond which a particular SPU, or set of SPUs, cannot read or write data. These sandboxes provide security against the corruption of data being processed by one SPU by data being processed by another SPU. These sandboxes also permit the downloading of software cells from network 104 into a particular sandbox without the possibility of the software cell corrupting data throughout the DRAM. In the present invention, the sandboxes are implemented in the hardware of the DRAMs and DMACs. By implementing these sandboxes in this hardware rather than in software, advantages in speed and security are obtained.

The PU of a PU controls the sandboxes assigned to the SPUs. Since the PU normally operates only trusted programs, such as an operating system, this scheme does not

jeopardize security. In accordance with this scheme, the PU builds and maintains a key control table. This key control table is illustrated in **Figure 33**. As shown in this figure, each entry in key control table **3302** contains an
5 identification (ID) **3304** for an SPU, an SPU key **3306** for that SPU and a key mask **3308**. The use of this key mask is explained below. Key control table **3302** preferably is stored in a relatively fast memory, such as a static random access memory (SRAM), and is associated with the DMAC. The
10 entries in key control table **3302** are controlled by the PU. When an SPU requests the writing of data to, or the reading of data from, a particular storage location of the DRAM, the DMAC evaluates the SPU key **3306** assigned to that SPU in key control table **3302** against a memory access key
15 associated with that storage location.

As shown in **Figure 34**, a dedicated memory segment **3410** is assigned to each addressable storage location **3406** of a DRAM **3402**. A memory access key **3412** for the storage location is stored in this dedicated memory segment. As
20 discussed above, a further additional dedicated memory segment **3408**, also associated with each addressable storage location **3406**, stores synchronization information for writing data to, and reading data from, the storage-
location.

25 In operation, an SPU issues a DMA command to the DMAC. This command includes the address of a storage location **3406** of DRAM **3402**. Before executing this command, the DMAC looks up the requesting SPU's key **3306** in key control table **3302** using the SPU's ID **3304**. The DMAC then compares the
30 SPU key **3306** of the requesting SPU to the memory access key

3412 stored in the dedicated memory segment **3410** associated with the storage location of the DRAM to which the SPU seeks access. If the two keys do not match, the DMA command is not executed. On the other hand, if the two keys match, the DMA command proceeds and the requested memory access is executed.

An alternative embodiment is illustrated in **Figure 35**. In this embodiment, the PU also maintains a memory access control table **3502**. Memory access control table **3502** contains an entry for each sandbox within the DRAM. In the particular example of **Figure 35**, the DRAM contains 64 sandboxes. Each entry in memory access control table **3502** contains an identification (ID) **3504** for a sandbox, a base memory address **3506**, a sandbox size **3508**, a memory access key **3510** and an access key mask **3512**. Base memory address **3506** provides the address in the DRAM which starts a particular memory sandbox. Sandbox size **3508** provides the size of the sandbox and, therefore, the endpoint of the particular sandbox.

Figure 36 is a flow diagram of the steps for executing a DMA command using key control table **3302** and memory access control table **3502**. In step **3602**, an SPU issues a DMA command to the DMAC for access to a particular memory location or locations within a sandbox. This command includes a sandbox ID **3504** identifying the particular sandbox for which access is requested. In step **3604**, the DMAC looks up the requesting SPU's key **3306** in key control table **3302** using the SPU's ID **3304**. In step **3606**, the DMAC uses the sandbox ID **3504** in the command to look up in memory access control table **3502** the memory access key **3510**

associated with that sandbox. In step **3608**, the DMAC compares the SPU key **3306** assigned to the requesting SPU to the access key **3510** associated with the sandbox. In step **3610**, a determination is made of whether the two keys match. If the two keys do not match, the process moves to step **3612** where the DMA command does not proceed and an error message is sent to either the requesting SPU, the PU or both. On the other hand, if at step **3610** the two keys are found to match, the process proceeds to step **3614** where the DMAC executes the DMA command.

The key masks for the SPU keys and the memory access keys provide greater flexibility to this system. A key mask for a key converts a masked bit into a wildcard. For example, if the key mask **3308** associated with an SPU key **3306** has its last two bits set to "mask," designated by, e.g., setting these bits in key mask **3308** to 1, the SPU key can be either a 1 or a 0 and still match the memory access key. For example, the SPU key might be **1010**. This SPU key normally allows access only to a sandbox having an access key of **1010**. If the SPU key mask for this SPU key is set to **0001**, however, then this SPU key can be used to gain access to sandboxes having an access key of either **1010** or **1011**. Similarly, an access key **1010** with a mask set to **0001** can be accessed by an SPU with an SPU key of either **1010** or **1011**. Since both the SPU key mask and the memory key mask can be used simultaneously, numerous variations of accessibility by the SPUs to the sandboxes can be established.

The present invention also provides a new programming model for the processors of system 101. This programming

model employs software cells 102. These cells can be transmitted to any processor on network 104 for processing. This new programming model also utilizes the unique modular architecture of system 101 and the processors of system 101.

Software cells are processed directly by the SPUs from the SPU's local storage. The SPUs do not directly operate on any data or programs in the DRAM. Data and programs in the DRAM are read into the SPU's local storage before the SPU processes these data and programs. The SPU's local storage, therefore, includes a program counter, stack and other software elements for executing these programs. The PU controls the SPUs by issuing direct memory access (DMA) commands to the DMAC.

The structure of software cells 102 is illustrated in **Figure 37**. As shown in this figure, a software cell, e.g., software cell **3702**, contains routing information section **3704** and body **3706**. The information contained in routing information section **3704** is dependent upon the protocol of network 104. Routing information section **3704** contains header **3708**, destination ID **3710**, source ID **3712** and reply ID **3714**. The destination ID includes a network address. Under the TCP/IP protocol, e.g., the network address is an Internet protocol (IP) address. Destination ID **3710** further includes the identity of the PU and SPU to which the cell should be transmitted for processing. Source ID **3712** contains a network address and identifies the PU and SPU from which the cell originated to enable the destination PU and SPU to obtain additional information regarding the cell if necessary. Reply ID **3714** contains a network address and

identifies the PU and SPU to which queries regarding the cell, and the result of processing of the cell, should be directed.

5 Cell body **3706** contains information independent of the network's protocol. The exploded portion of **Figure 37** shows the details of cell body **3706**. Header **3720** of cell body **3706** identifies the start of the cell body. Cell interface **3722** contains information necessary for the cell's utilization. This information includes global unique ID
10 **3724**, required SPUs **3726**, sandbox size **3728** and previous cell ID **3730**.

Global unique ID **3724** uniquely identifies software cell **3702** throughout network 104. Global unique ID **3724** is generated on the basis of source ID **3712**, e.g. the unique
15 identification of a PU or SPU within source ID **3712**, and the time and date of generation or transmission of software cell **3702**. Required SPUs **3726** provides the minimum number of SPUs required to execute the cell. Sandbox size **3728**
20 provides the amount of protected memory in the required SPUs' associated DRAM necessary to execute the cell. Previous cell ID **3730** provides the identity of a previous cell in a group of cells requiring sequential execution, e.g., streaming data.

Implementation section **3732** contains the cell's core
25 information. This information includes DMA command list **3734**, programs **3736** and data **3738**. Programs **3736** contain the programs to be run by the SPUs (called "spulets"), e.g., SPU programs **3760** and **3762**, and data **3738** contain the data to be processed with these programs. DMA command list

3734 contains a series of DMA commands needed to start the programs. These DMA commands include DMA commands **3740**, **3750**, **3755** and **3758**. The PU issues these DMA commands to the DMAC.

5 DMA command **3740** includes VID **3742**. VID **3742** is the virtual ID of an SPU which is mapped to a physical ID when the DMA commands are issued. DMA command **3740** also includes load command **3744** and address **3746**. Load command **3744** directs the SPU to read particular information from the
10 DRAM into local storage. Address **3746** provides the virtual address in the DRAM containing this information. The information can be, e.g., programs from programs section **3736**, data from data section **3738** or other data. Finally, DMA command **3740** includes local storage address **3748**. This
15 address identifies the address in local storage where the information should be loaded. DMA commands **3750** contain similar information. Other DMA commands are also possible.

DMA command list **3734** also includes a series of kick commands, e.g., kick commands **3755** and **3758**. Kick commands
20 are commands issued by a PU to an SPU to initiate the processing of a cell. DMA kick command **3755** includes virtual SPU ID **3752**, kick command **3754** and program counter **3756**. Virtual SPU ID **3752** identifies the SPU to be kicked, kick command **3754** provides the relevant kick command and
25 program counter **3756** provides the address for the program counter for executing the program. DMA kick command **3758** provides similar information for the same SPU or another SPU.

As noted, the PUs treat the SPUs as independent processors, not co-processors. To control processing by the SPUs, therefore, the PU uses commands analogous to remote procedure calls. These commands are designated "SPU Remote Procedure Calls" (SRPCs). A PU implements an SRPC by issuing a series of DMA commands to the DMAC. The DMAC loads the SPU program and its associated stack frame into the local storage of an SPU. The PU then issues an initial kick to the SPU to execute the SPU Program.

Figure 38 illustrates the steps of an SRPC for executing an spulet. The steps performed by the PU in initiating processing of the spulet by a designated SPU are shown in the first portion **3802** of **Figure 38**, and the steps performed by the designated SPU in processing the spulet are shown in the second portion **3804** of **Figure 38**.

In step **3810**, the PU evaluates the spulet and then designates an SPU for processing the spulet. In step **3812**, the PU allocates space in the DRAM for executing the spulet by issuing a DMA command to the DMAC to set memory access keys for the necessary sandbox or sandboxes. In step **3814**, the PU enables an interrupt request for the designated SPU to signal completion of the spulet. In step **3818**, the PU issues a DMA command to the DMAC to load the spulet from the DRAM to the local storage of the SPU. In step **3820**, the DMA command is executed, and the spulet is read from the DRAM to the SPU's local storage. In step **3822**, the PU issues a DMA command to the DMAC to load the stack frame associated with the spulet from the DRAM to the SPU's local storage. In step **3823**, the DMA command is executed, and the stack frame is read from the DRAM to the SPU's local

storage. In step **3824**, the PU issues a DMA command for the DMAC to assign a key to the SPU to allow the SPU to read and write data from and to the hardware sandbox or sandboxes designated in step **3812**. In step **3826**, the DMAC
5 updates the key control table (KTAB) with the key assigned to the SPU. In step **3828**, the PU issues a DMA command "kick" to the SPU to start processing of the program. Other DMA commands may be issued by the PU in the execution of a particular SRPC depending upon the particular spulet.

10 As indicated above, second portion **3804** of **Figure 38** illustrates the steps performed by the SPU in executing the spulet. In step **3830**, the SPU begins to execute the spulet in response to the kick command issued at step **3828**. In step **3832**, the SPU, at the direction of the spulet,
15 evaluates the spulet's associated stack frame. In step **3834**, the SPU issues multiple DMA commands to the DMAC to load data designated as needed by the stack frame from the DRAM to the SPU's local storage. In step **3836**, these DMA commands are executed, and the data are read from the DRAM
20 to the SPU's local storage. In step **3838**, the SPU executes the spulet and generates a result. In step **3840**, the SPU issues a DMA command to the DMAC to store the result in the DRAM. In step **3842**, the DMA command is executed and the result of the spulet is written from the SPU's local
25 storage to the DRAM. In step **3844**, the SPU issues an interrupt request to the PU to signal that the SRPC has been completed.

The ability of SPUs to perform tasks independently under the direction of a PU enables a PU to dedicate a
30 group of SPUs, and the memory resources associated with a

group of SPUs, to performing extended tasks. For example, a PU can dedicate one or more SPUs, and a group of memory sandboxes associated with these one or more SPUs, to receiving data transmitted over network 104 over an extended period and to directing the data received during this period to one or more other SPUs and their associated memory sandboxes for further processing. This ability is particularly advantageous to processing streaming data transmitted over network 104, e.g., streaming MPEG or streaming ATRAC audio or video data. A PU can dedicate one or more SPUs and their associated memory sandboxes to receiving these data and one or more other SPUs and their associated memory sandboxes to decompressing and further processing these data. In other words, the PU can establish a dedicated pipeline relationship among a group of SPUs and their associated memory sandboxes for processing such data.

In order for such processing to be performed efficiently, however, the pipeline's dedicated SPUs and memory sandboxes should remain dedicated to the pipeline during periods in which processing of spulets comprising the data stream does not occur. In other words, the dedicated SPUs and their associated sandboxes should be placed in a reserved state during these periods. The reservation of an SPU and its associated memory sandbox or sandboxes upon completion of processing of an spulet is called a "resident termination." A resident termination occurs in response to an instruction from a PU.

Figures. 39, 40A and 40B illustrate the establishment of a dedicated pipeline structure comprising a group of SPUs and their associated sandboxes for the processing of

streaming data, e.g., streaming MPEG data. As shown in **Figure 39**, the components of this pipeline structure include PU **3902** and DRAM **3918**. PU **3902** includes PU **3904**, DMAC **3906** and a plurality of SPUs, including SPU **3908**, SPU **3910** and SPU **3912**. Communications among PU **3904**, DMAC **3906** and these SPUs occur through PU bus **3914**. Wide bandwidth bus **3916** connects DMAC **3906** to DRAM **3918**. DRAM **3918** includes a plurality of sandboxes, e.g., sandbox **3920**, sandbox **3922**, sandbox **3924** and sandbox **3926**.

Figure 40A illustrates the steps for establishing the dedicated pipeline. In step **4010**, PU **3904** assigns SPU **3908** to process a network spulet. A network spulet comprises a program for processing the network protocol of network 104. In this case, this protocol is the Transmission Control Protocol/Internet Protocol (TCP/IP). TCP/IP data packets conforming to this protocol are transmitted over network 104. Upon receipt, SPU **3908** processes these packets and assembles the data in the packets into software cells 102. In step **4012**, PU **3904** instructs SPU **3908** to perform resident terminations upon the completion of the processing of the network spulet. In step **4014**, PU **3904** assigns PUs **3910** and **3912** to process MPEG spulets. In step **4015**, PU **3904** instructs SPUs **3910** and **3912** also to perform resident terminations upon the completion of the processing of the MPEG spulets. In step **4016**, PU **3904** designates sandbox **3920** as a source sandbox for access by SPU **3908** and SPU **3910**. In step **4018**, PU **3904** designates sandbox **3922** as a destination sandbox for access by SPU **3910**. In step **4020**, PU **3904** designates sandbox **3924** as a source sandbox for access by SPU **3908** and SPU **3912**. In step **4022**, PU **3904** designates sandbox **3926** as a destination sandbox for access by SPU

3912. In step 4024, SPU 3910 and SPU 3912 send synchronize read commands to blocks of memory within, respectively, source sandbox 3920 and source sandbox 3924 to set these blocks of memory into the blocking state. The process
5 finally moves to step 4028 where establishment of the dedicated pipeline is complete and the resources dedicated to the pipeline are reserved. SPUs 3908, 3910 and 3912 and their associated sandboxes 3920, 3922, 3924 and 3926, therefore, enter the reserved state.

10 **Figure 40B** illustrates the steps for processing streaming MPEG data by this dedicated pipeline. In step 4030, SPU 3908, which processes the network spulet, receives in its local storage TCP/IP data packets from network 104. In step 4032, SPU 3908 processes these TCP/IP
15 data packets and assembles the data within these packets into software cells 102. In step 4034, SPU 3908 examines header 3720 (**Figure 37**) of the software cells to determine whether the cells contain MPEG data. If a cell does not contain MPEG data, then, in step 4036, SPU 3908 transmits
20 the cell to a general purpose sandbox designated within DRAM 3918 for processing other data by other SPUs not included within the dedicated pipeline. SPU 3908 also notifies PU 3904 of this transmission.

25 On the other hand, if a software cell contains MPEG data, then, in step 4038, SPU 3908 examines previous cell ID 3730 (**Figure 37**) of the cell to identify the MPEG data stream to which the cell belongs. In step 4040, SPU 3908 chooses an SPU of the dedicated pipeline for processing of the cell. In this case, SPU 3908 chooses SPU 3910 to
30 process these data. This choice is based upon previous cell

ID **3730** and load balancing factors. For example, if previous cell ID **3730** indicates that the previous software cell of the MPEG data stream to which the software cell belongs was sent to SPU **3910** for processing, then the present software cell normally also will be sent to SPU **3910** for processing. In step **4042**, SPU **3908** issues a synchronize write command to write the MPEG data to sandbox **3920**. Since this sandbox previously was set to the blocking state, the MPEG data, in step **4044**, automatically is read from sandbox **3920** to the local storage of SPU **3910**. In step **4046**, SPU **3910** processes the MPEG data in its local storage to generate video data. In step **4048**, SPU **3910** writes the video data to sandbox **3922**. In step **4050**, SPU **3910** issues a synchronize read command to sandbox **3920** to prepare this sandbox to receive additional MPEG data. In step **4052**, SPU **3910** processes a resident termination. This processing causes this SPU to enter the reserved state during which the SPU waits to process additional MPEG data in the MPEG data stream.

Other dedicated structures can be established among a group of SPUs and their associated sandboxes for processing other types of data. For example, as shown in **Figure 41**, a dedicated group of SPUs, e.g., SPUs **4102**, **4108** and **4114**, can be established for performing geometric transformations upon three dimensional objects to generate two dimensional display lists. These two dimensional display lists can be further processed (rendered) by other SPUs to generate pixel data. To perform this processing, sandboxes are dedicated to SPUs **4102**, **4108** and **4114** for storing the three dimensional objects and the display lists resulting from the processing of these objects. For example, source

sandboxes **4104**, **4110** and **4116** are dedicated to storing the three dimensional objects processed by, respectively, SPU **4102**, SPU **4108** and SPU **4114**. In a similar manner, destination sandboxes **4106**, **4112** and **4118** are dedicated to storing the display lists resulting from the processing of these three dimensional objects by, respectively, SPU **4102**, SPU **4108** and SPU **4114**.

Coordinating SPU **4120** is dedicated to receiving in its local storage the display lists from destination sandboxes **4106**, **4112** and **4118**. SPU **4120** arbitrates among these display lists and sends them to other SPUs for the rendering of pixel data.

The processors of system 101 also employ an absolute timer. The absolute timer provides a clock signal to the SPUs and other elements of a PU which is both independent of, and faster than, the clock signal driving these elements. The use of this absolute timer is illustrated in **Figure 42**.

As shown in this figure, the absolute timer establishes a time budget for the performance of tasks by the SPUs. This time budget provides a time for completing these tasks which is longer than that necessary for the SPUs' processing of the tasks. As a result, for each task, there is, within the time budget, a busy period and a standby period. All spulets are written for processing on the basis of this time budget regardless of the SPUs' actual processing time or speed.

For example, for a particular SPU of a PU, a particular task may be performed during busy period **4202** of time budget **4204**. Since busy period **4202** is less than time budget **4204**, a standby period **4206** occurs during the time budget. During this standby period, the SPU goes into a sleep mode during which less power is consumed by the SPU.

The results of processing a task are not expected by other SPUs, or other elements of a PU, until a time budget **4204** expires. Using the time budget established by the absolute timer, therefore, the results of the SPUs' processing always are coordinated regardless of the SPUs' actual processing speeds.

In the future, the speed of processing by the SPUs will become faster. The time budget established by the absolute timer, however, will remain the same. For example, as shown in **Figure 42**, an SPU in the future will execute a task in a shorter period and, therefore, will have a longer standby period. Busy period **4208**, therefore, is shorter than busy period **4202**, and standby period **4210** is longer than standby period **4206**. However, since programs are written for processing on the basis of the same time budget established by the absolute timer, coordination of the results of processing among the SPUs is maintained. As a result, faster SPUs can process programs written for slower SPUs without causing conflicts in the times at which the results of this processing are expected.

In lieu of an absolute timer to establish coordination among the SPUs, the PU, or one or more designated SPUs, can analyze the particular instructions or microcode being

executed by an SPU in processing an spulet for problems in the coordination of the SPUs' parallel processing created by enhanced or different operating speeds. "No operation" ("NOOP") instructions can be inserted into the instructions and executed by some of the SPUs to maintain the proper sequential completion of processing by the SPUs expected by the spulet. By inserting these NOOPs into the instructions, the correct timing for the SPUs' execution of all instructions can be maintained.

Figure 43 is a block diagram illustrating a processing element having a main processor and a plurality of secondary processors sharing a system memory. Processor Element (PE) **4305** includes processing unit (PU) **4310**, which, in one embodiment, acts as the main processor and runs an operating system. Processing unit **4310** may be, for example, a Power PC core executing a Linux operating system. PE **4305** also includes a plurality of synergistic processing complex's (SPCs) such as SPCs **4345**, **4365**, and **4385**. The SPCs include synergistic processing units (SPUs) that act as secondary processing units to PU **4310**, a memory storage unit, and local storage. For example, SPC **4345** includes SPU **4360**, MMU **4355**, and local storage **4359**; SPC **4365** includes SPU **4370**, MMU **4375**, and local storage **4379**; and SPC **4385** includes SPU **4390**, MMU **4395**, and local storage **4399**.

Each SPC may be configured to perform a different task, and accordingly, in one embodiment, each SPC may be accessed using different instruction sets. If PE **4305** is being used in a wireless communications system, for example, each SPC may be responsible for separate

processing tasks, such as modulation, chip rate processing, encoding, network interfacing, etc. In another embodiment, the SPCs may have identical instruction sets and may be used in parallel with each other to perform operations benefiting from parallel processing.

PE **4305** may also include level 2 cache, such as L2 cache **4315**, for the use of PU **4310**. In addition, PE **4305** includes system memory **4320**, which is shared between PU **4310** and the SPUs. System memory **4320** may store, for example, an image of the running operating system (which may include the kernel), device drivers, I/O configuration, etc., executing applications, as well as other data. System memory **4320** includes the local storage units of one or more of the SPCs, which are mapped to a region of system memory **4320**. For example, local storage **4359** may be mapped to mapped region **4335**, local storage **4379** may be mapped to mapped region **4340**, and local storage **4399** may be mapped to mapped region **4342**. PU **4310** and the SPCs communicate with each other and system memory **4320** through bus **4317** that is configured to pass data between these devices.

The MMUs are responsible for transferring data between an SPU's local store and the system memory. In one embodiment, an MMU includes a direct memory access (DMA) controller configured to perform this function. PU **4310** may program the MMUs to control which memory regions are available to each of the MMUs. By changing the mapping available to each of the MMUs, the PU may control which SPU has access to which region of system memory **4320**. In this manner, the PU may, for example, designate regions of the system memory as private for the exclusive use of a

particular SPU. In one embodiment, the SPUs' local stores may be accessed by PU **4310** as well as by the other SPUs using the memory map. In one embodiment, PU **4310** manages the memory map for the common system memory **4320** for all
5 the SPUs. The memory map table may include PU **4310**'s L2 Cache **4315**, system memory **4320**, as well as the SPUs' shared local stores.

In one embodiment, the SPUs process data under the control of PU **4310**. The SPUs may be, for example, digital
10 signal processing cores, microprocessor cores, micro controller cores, etc., or a combination of the above cores. Each one of the local stores is a storage area associated with a particular SPU. In one embodiment, each SPU can configure its local store as a private storage
15 area, a shared storage area, or an SPU may configure its local store as a partly private and partly shared storage.

For example, if an SPU requires a substantial amount of local memory, the SPU may allocate 100% of its local store to private memory accessible only by that SPU. If,
20 on the other hand, an SPU requires a minimal amount of local memory, the SPU may allocate 10% of its local store to private memory and the remaining 90% to shared memory. The shared memory is accessible by PU **4310** and by the other SPUs. An SPU may reserve part of its local store in order
25 for the SPU to have fast, guaranteed memory access when performing tasks that require such fast access. The SPU may also reserve some of its local store as private when processing sensitive data, as is the case, for example, when the SPU is performing encryption/decryption.

Figure 44 is a block diagram illustrating a processing element having a main processor and a plurality of secondary processors sharing a system memory. Processor Element (PE) **4405** includes processing unit (PU) **4410**, which, in one embodiment, acts as the main processor and runs the operating system. Processing unit **4410** may be, for example, a Power PC core executing a Linux operating system. PE **4405** also includes a plurality of synergistic processing complex's (SPCs) such as SPCs **4445** through **4485**. Each SPC includes a synergistic processing unit (SPU) that act as secondary processing units to PU **4410**, a memory storage unit, and local storage. For example, SPC **4445** includes SPU **4460**, MMU **4455**, and local storage **4459**; SPC **4465** includes SPU **4470**, MMU **4475**, and local storage **4479**; and SPC **4485** includes SPU **4490**, MMU **4495**, and local storage **4499**.

In one embodiment, the SPUs process data under the control of PU **4410**. The SPUs may be, for example, digital signal processing cores, microprocessor cores, micro controller cores, etc., or a combination of the above cores. In one embodiment, each one of the local stores is a storage area associated with a particular SPU. Each SPU can configure its local store as a private storage area, a shared storage area, or an SPU's local store may be partly private and partly shared.

For example, if an SPU requires a substantial amount of local memory, the SPU may allocate 100% of its local store to private memory accessible only by that SPU. If, on the other hand, an SPU requires a minimal amount of local memory, the SPU may allocate 10% of its local store

to private memory and the remaining 90% to shared memory. The shared memory is accessible by PU **4410** and by the other SPU's. An SPU may reserve part of its local store in order for the SPU to have fast, guaranteed access to some memory when performing tasks that require such fast access. The SPU may also reserve some of its local store as private when processing sensitive data, as is the case, for example, when the SPU is performing encryption/decryption.

The MMUs are responsible for transferring data between an SPU's local store and the system memory. In one embodiment, an MMU includes a direct memory access (DMA) controller configured to perform this function.

Each SPC may be set up to perform a different task, and accordingly, in one embodiment, each SPC may be accessed using different instruction sets. If PE **4405** is being used in a wireless communications system, for example, each SPC may be responsible for separate processing tasks, such as modulation, chip rate processing, encoding, network interfacing, etc. In another embodiment, each SPC may have identical instruction sets and may be used in parallel to perform operations benefiting from parallel processes.

The shared portion of the SPU's local stores may be accessed by PU **4410** as well as by the other SPU's by mapping each shared region to system memory **4420**. In one embodiment, PU **4410** manages the memory map for the common system memory **4420**. The memory map table may include PU **4410**'s L2 Cache **4415**, system memory **4420**, as well as the SPU's shared local stores.

A portion of system memory **4420** as shown is occupied by the operating system (OS **4425**). System Memory **4425** also contains data **4440**, which represents data to be processed by SPU **4410** as well as by the SPUs. In one embodiment, a process executing on the PU receives a request for a task involving the processing of large data. The PU first determines an optimum method for performing the task as well as an optimum placement of the data in common system memory **4420**. The PU may then initiate a transfer of the data to be processed from disk **4435** to system memory **4420**. In one embodiment, the PU arranges the data in system memory **4425** in data blocks the size of the registers of the SPUs. In one embodiment, the SPUs may have 128 registers, each register being 128 bits long.

The PU then searches for available SPUs and assigns blocks of data to any available SPUs for processing of the data. The SPUs can access the common system memory (through a DMA command, for example) transfer the data to the SPUs' local store, and perform the assigned operations. After processing the data, the SPUs may transfer the data (using DMA again, for example) back to common system memory **4420**. This procedure may be repeated as SPUs become available until all the data blocks have been processed.

Figure 45 is a flowchart illustrating a method for loading data from the disk to the common system memory. Processing begins at **4500** whereupon, at step **4510**, a task request is received by an executing application. The location of the data to be processed on disk **4540** is also received. The data may be a large matrix equation, for

example, and the requested task may be to obtain a solution to the matrix equation.

At step **4515**, an optimum method for performing the requested task is determined. In addition, an optimum
5 block size for dividing the data is also determined. In one embodiment, the block size is chosen to be the size of the registers of the SPUs in anticipation of the parallel processing of the data by the SPUs.

In step **4520**, the first data block is selected, and at
10 step **4525**, the first data block (block **4551**, for example) is loaded in data **4550** region in system memory **4545**. A determination is then made as to whether more data blocks remain on disk **4540** requiring transfer into common system memory **4545** at decision **4530**. If there are no more blocks
15 of data to be transferred, decision **4530** branches to "no" branch **4534** and processing ends at **4599**.

If there are more data blocks to be transferred, decision **4530** branches to "yes" branch **4532** whereupon, at
20 step **4535**, the next data block is loaded from disk into the common system memory. Processing then loops back to decision **4530** to determine whether there are more data blocks requiring transfer.

Figure 46 is a flowchart illustrating a process for parallel processing data in a common system memory with a
25 plurality of processors. Processing begins at **4600** whereupon, at step **4620**, the PU determines a set of SPU operations for performing the requested task, and at step

4625, the PU creates a table of a set of operations for completing the requested task.

At step **4630**, the PU determines an available SPU and sends a request to the available SPU to process a block of data. In one embodiment, the PU may send a request to the SPU by placing an appropriate value in the SPU's mailbox—a region of SPU memory that is continuously monitored by the SPU for assigned tasks.

At step **4645**, the SPU transfers the block of data to the SPU's local store. In one embodiment, the SPU may transfer the block of data using a DMA command. At step **4650**, the SPU loads the data block into the SPU's registers, and the SPU processes the data according to instructions also received from the PU. At step **4655**, the SPU transfers the processed data block back to the common system memory. In one embodiment, the SPU may do so using a DMA command.

A determination is then made as to whether more block operations are pending at decision **4660**. If more block operations are pending, decision **4660** branches to "yes" branch **4662** whereupon processing loops back to step **4630** where more SPUs are assigned data blocks for processing.

If no more block operations are pending, decision **4660** branches to "no" branch **4664** whereupon another determination is made as to whether a solution to the assigned task has been reached at decision **4665**. If a solution has not yet been reached, decision **4665** branches

to "no" branch **4664** whereupon processing loops back to step **4620** where a new set of SPU operations is determined.

If a solution has been reached, decision **4665** branches to "yes" branch **4662** whereupon, at step **4670**, the PU
5 finalizes the processing. The PU may, for example, compute the final solution to the task by using data from all the processed data blocks. Processing ends at **4699**.

Figure 47 is a block diagram illustrating the creation, from a system of linear equations, of an
10 equivalent augmented matrix. Box **4710** shows the original system of linear equations. A system of linear equations includes n unknown variables (x 's) linearly related by a set of n equations. Each variable in each equation has a
15 coefficient (a 's), and each equation includes a constant term (b 's). To solve the system of linear equations, a value must be found for each of the unknown variables such that all the equations in the system are satisfied. A
unique solution to the system of linear equations is guaranteed to exist unless the determinant of the system's
20 equivalent matrix (see discussion below) is zero.

Box **4715** shows how the system of linear equations may be thought as an equivalent matrix equation. The matrix
equation shown is equivalent to the system of linear
equations since a solution to the matrix equation is also a
25 solution to the system of linear equations. As shown in Box **4720**, the matrix equation can be written in the simple form, $\mathbf{ax}=\mathbf{b}$, where \mathbf{a} represents a matrix of all the coefficients of the unknown variables, \mathbf{x} is a single-column

vector of the unknown variables, and **b** is a single-column vector of the constants.

Block **4725** shows how the coefficient matrix may be combined with the constant vector to yield the augmented matrix. In order to solve the system of linear equations, matrix operations are applied to the matrix equation such as replacing rows and columns by linear combinations of other rows and columns. To keep the resulting matrix equation equivalent (having the same solution as the previous matrix equation), the same matrix operations should be applied to the constant vector, **b**. Thus, it is more convenient to apply these matrix operations to the augmented matrix, such that the operations are also applied to the constant vector, **b**.

Figure **48** is a block diagram illustrating division of the linear equations coefficients into data blocks and the loading of the data blocks into a common memory. In one embodiment, the data blocks are equal in size to the registers of the secondary processors (SPUs). Box **4810** shows the undivided augmented matrix, and box **4815** shows the augmented matrix divided into coefficient blocks. In the example shown, each one of the blocks contains four coefficients each.

The coefficient blocks are then loaded in common RAM **4860**. Common RAM **4860** may be accessed by the one or more processors of the system, which facilitates the sharing of data among the one or more processors. In one embodiment, coefficients from the same block are loaded into neighboring positions in common RAM **4860** in order to

facilitate the processing the matrix coefficients on a block-by-block basis in a multi-processor environment. For example, the coefficients from block **4820** are loaded into memory range **4840**, the coefficients from block **4825** are loaded into memory range **4845**, the coefficients from block **4830** are loaded into memory range **4850**, the coefficients from block **4835** are loaded into memory range **4855**, etc.

Figure 49 is a table illustrating examples of matrix operations that may be used to solve the matrix equation and thus the system of linear equations. The matrix operations in table **4900** may be created by one of the processors (such as a processor designated as the main processor) using one of the methods for solving a matrix equation.

In one embodiment, the matrix equation may be solved by LU decomposition. LU decomposition involves factoring the coefficient matrix, **A**, into the product **L·U** where **L** is a lower diagonal matrix and **U** is an upper triangular matrix. A solution may then be easily obtained by solving for the vector **U·x** in the equation $L \cdot (U \cdot x) = b$ and then solving the **U·x** equation for **x**. The above method is also called backward-forward substitution. The LU decomposition algorithm is well-known.

Another method for solving a system of linear equations is Gauss elimination. The Gauss elimination method involves repeatedly transforming the matrix, by applying matrix operations, into equivalent matrices until the matrix is upper triangular. An upper triangular matrix has elements that are equal to 0 everywhere but the

elements along the diagonal and the elements above the diagonal. The unknown variables may then be easily computed from the upper diagonal matrix using back substitution. Matrix transformations typically involve replacing a row or column with a linear combination of the row or column and any other row or column. Such linear transformations always yield equivalent matrices—matrices whose solutions are the same as those of the original matrix.

Column 1 of table **4900** contains a list of such transformations/operations. Column 2 contains, for each of the matrix operations, a list of blocks that contain rows or columns that are affected by the operation. Column 3 contains a record of whether the operations have been applied to the particular block, and Column 4 contains a list of which SPU is processing or has processed the particular block/operation. Free SPUs returning for a new assignment can be reassigned using the information in Column 4 to determine pending operations for a particular block.

Figure 50 is a block diagram illustrating how the SPUs access the common memory to perform matrix operations on blocks of coefficients. **Figure 50** shows a system having a main processor, PU **5010**, and a number of secondary processors, such as SPU **5010**, SPU **5015**, SPU **5020**,..., and SPU **5025**. For example, SPU **5010** may be accessing block **5050**, SPU **5015** may be accessing block **5040**, SPU **5020** may be accessing block **5055**, and SPU **5025** may be accessing block **5045**.

Figure 51 is a flowchart illustrating the receiving of the linear equations coefficients and the loading of the coefficients into the common memory. Processing begins at **5100** whereupon at step **5110**, the number of unknown variables (which is also the number equations) for a system of linear equations is received. At step **5115**, the coefficients of the unknown variables for the system of linear equations are received, and at step **5120**, the coefficients are arranged into a matrix form. Generally, a system of n linear equations can be written as:

$$\begin{array}{cccccc} a_{11}x_1 & + & a_{12}x_2 & + & \cdots & + & a_{1n}x_n & = & b_1 \\ a_{21}x_1 & + & a_{22}x_2 & + & \cdots & + & a_{2n}x_n & = & b_2 \\ \vdots & & \vdots & & \vdots & & \vdots & & \vdots \\ a_{n1}x_1 & + & a_{n2}x_2 & + & \cdots & + & a_{nn}x_n & = & b_n \end{array}$$

where x_1-x_n are the n unknown variables, the a 's are the coefficients of the unknown variables, and b 's are the constant terms in each equation. The solutions to the above linear equations are also the solutions to the equivalent matrix equation, $\mathbf{ax}=\mathbf{b}$, where

$$\mathbf{a} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}, \quad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}, \quad \text{and} \quad \mathbf{b} = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_n \end{bmatrix}.$$

The matrix equation is equivalent to the system of linear equations since the solutions to the matrix equations are the same as the solutions to the system of linear equations. By operating on the \mathbf{a} matrix to obtain solutions to the matrix equation, solutions to the system of linear equations are also obtained.

At step **5120**, an augmented matrix consisting of the coefficients, \mathbf{a} , and the constants terms, \mathbf{b} , is formed:

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} & b_1 \\ a_{21} & a_{22} & \cdots & a_{2n} & b_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} & b_n \end{bmatrix}.$$

For the matrix transformations to continue yielding equivalent matrices, the matrix transformations should be applied to the coefficients as well as the constant terms.

5 Thus, the augmented matrix is better form to work with.

At step **5130**, an optimum size for the coefficient blocks is determined. Prior to applying matrix operations, the matrix is divided into a number of blocks to facilitate applying the matrix operations by multiple processors. The size of the block may depend on the size of the matrix, the method chosen to solve the matrix, the number of available SPU's, etc. The size is chosen to yield the most efficient solving of the matrix operation. In another embodiment, the size of the data block may be chosen to be the size of the registers of the SPU's to facilitate the processing of the data blocks by the SPU's.

At step **5135**, the matrix is divided into blocks according to the determination made at step **5130**, and at step **5140**, the coefficient blocks are loaded into a common memory. In one embodiment, the coefficients blocks are loaded sequentially. The common memory is accessible by all the SPU's that will be sharing the task of solving the matrix equation. Processing ends at **5199**.

Figure 52 is a flowchart illustrating the PU determining a set of matrix operations to solve the linear differential equations. In one embodiment, the PU may use

the Gauss elimination method to obtain a solution to the matrix equation. The Gauss elimination method involves transforming the matrix into upper triangular form by replacing a row or a column by a linear combination of the row or column and one or more of the other rows or columns respectively. At each stage, an equivalent matrix is formed: one whose solution is the same as the one for the previous matrix.

Processing begins at **5200** whereupon, at step **5210**, the PU analyzes the coefficients stored in the common memory, and at step **5215**, the PU determines the optimum method for solving the linear equations. For example, the PU may determine that Gauss elimination is the best method.

At step **5220**, the PU determines a set of matrix operations for solving the matrix equation. At step **5225**, the PU creates a table containing a list of all the determined matrix operations. The table may be created in order to keep track of which operations have been completed, for which block, and by which SPU. An example of such a table is shown in **Figure 49**.

At step **5230**, the PU programs the SPUs to perform the matrix operations. In one embodiment, the SPUs are flexible processors that can be optimized for performing certain tasks such as applying matrix operations to coefficient blocks. At step **5235**, the PU instructs the SPUs to perform the matrix operations on a block-by-block basis, and at step **5240**, the SPUs begin performing the assigned tasks. More details on the processing that takes

place at step **5240** are provided in the flowchart illustrated in **Figure 53**.

5 After the first set of matrix operations is performed, a determination is made as to whether a matrix solution has been reached at decision **5245**. If a matrix solution has not been reached, decision **5245** branches to "no" branch **5255** whereupon processing returns to step **5220** where the PU determines a new set of matrix operations. If a matrix solution has been reached, decision **5245** branches to "yes" 10 branch **5250** whereupon processing continues to step **5260**.

At step **5260**, the PU computes the solutions to the matrix equation (which are also the solutions to the system of linear equations) from the resulting matrix. Processing ends at **5299**.

15 **Figure 53** is a flowchart illustrating the SPUs performing the matrix operations on a block-by-block basis. Processing begins at **5300** whereupon, at step **5310**, a free SPU—an SPU that is not currently involved in any other task—reports ready to perform pending matrix operations on 20 blocks of coefficients. A determination is then made as to whether more block operations are pending at decision **5315**. If there are no more block operations pending, decision **5315** branches to "no" branch **5325** whereupon, at step **5355**, the PU is informed that all pending matrix operations have 25 been completed. Processing ends at **5399**. As shown in the flowchart of **Figure 52**, if at this time, a matrix solution has not been obtained, the PU may generate additional matrix operations.

If there are more block operations pending, decision **5315** branches to "yes" branch **5320** whereupon the SPU identifies a pending matrix operation and indicates that SPU is in the process of completing the block operation.

5 In one embodiment, the SPU may identify a pending matrix operation and indicate the operation is being performed by using the table of tasks shown in **Figure 49**.

At step **5335**, the SPU accesses the common memory and loads one or more of the coefficients in its assigned block to begin the processing. In one embodiment, one or more of

10 the SPUs may access the memory through a direct memory access unit. At step **5340**, the matrix operation is applied to one or more loaded coefficients. At step **5345**, the result of the matrix operation on the one or more

15 coefficients is loaded back into the common memory. By doing so, the result is now accessible by the PU as well as by the other SPUs and there is no need to transmit the result to the PU or to the other SPUs.

A determination is then made as to whether there are

20 more coefficients requiring processing at decision **5360**. If there are more coefficients requiring processing, decision **5360** branches to "yes" branch **5365** whereupon processing return to step **5335** where one or more coefficients are loaded from the common memory. If there

25 are no more coefficients requiring processing, decision **5360** branches to "no" branch **5370** whereupon processing returns to step **5310**. At step **5310**, the SPU reports ready to perform additional sets of block operations.

While particular embodiments of the present invention have been shown and described, it will be obvious to those skilled in the art that, based upon the teachings herein, changes and modifications may be made without departing from this invention and its broader aspects and, therefore, the appended claims are to encompass within their scope all such changes and modifications as are within the true spirit and scope of this invention. Furthermore, it is to be understood that the invention is solely defined by the appended claims. It will be understood by those with skill in the art that if a specific number of an introduced claim element is intended, such intent will be explicitly recited in the claim, and in the absence of such recitation no such limitation is present. For a non-limiting example, as an aid to understanding, the following appended claims contain usage of the introductory phrases "at least one" and "one or more" to introduce claim elements. However, the use of such phrases should not be construed to imply that the introduction of a claim element by the indefinite articles "a" or "an" limits any particular claim containing such introduced claim element to inventions containing only one such element, even when the same claim includes the introductory phrases "one or more" or "at least one" and indefinite articles such as "a" or "an"; the same holds true for the use in the claims of definite articles.
